

Tapsi Doctor:

Migrated 20+ services from IIS to a Kubernetes-based environment — handled most of the configuration work myself and stayed closely aligned with the DevOps team throughout the process.

Worked on improving application performance pretty significantly. Before my changes, the system was struggling with around 100 concurrent users. After optimizing queries, services, and the overall architecture, it got to a point where it could comfortably handle 10,000 users.

Moved inter-service communication onto Kafka for 6-7 critical services that were directly impacting system latency and user experience — shifting from synchronous to asynchronous messaging and enabling the system to handle tens of thousands of requests per second between services, making the whole architecture significantly more resilient and easier to scale.

Attended multiple coordination meetings with external services and third-party vendors, then took ownership of implementing the integrations afterward.

Solely responsible for conducting technical interviews for senior backend engineer candidates — evaluated system design knowledge, coding skills, and architectural thinking independently, with hiring decisions based directly on my assessment.

Consistently delivered features under tight, business-driven deadlines — often receiving requirements with less than 24 hours notice and shipping production-ready code on time without compromising quality.

Mentored 3 junior developers from onboarding to independent contribution — defined their tasks progressively, conducted regular code reviews, and ran technical assessments to track their growth until each one reached a point where they could deliver production-ready code autonomously.

Helped bring up the staging environment in collaboration with the DevOps team.

Designed and implemented a unified API Gateway with a single Swagger interface across all microservices from scratch, simplifying frontend integration and reducing complexity for the development team.

Owned the full release process for multiple services — wrote and maintained Dockerfiles, managed versioning and tagging strategy, and handled deployments independently. In the absence of a proper Git

flow, I took it upon myself to establish a consistent tagging and versioning process using Git commands, bringing some structure to the release cycle where there wasn't any before.

Tourism Bank:

Designed and developed an internal framework to simplify recurring development tasks and establish reusable patterns across multiple projects, helping improve development efficiency and code consistency.

Took ownership of the integration process with the mobile application team, participating in technical discussions, defining API contracts, resolving integration challenges, and supporting the delivery process from development to production.

Developed backend services for mobile top-up and internet package purchases, including business logic implementation, API design, and integration with external service providers.

Defined API contracts and collaborated with client applications to ensure seamless integration

Bime Markazi:

Migrated a large-scale insurance platform with extensive business rules from hundreds of stored procedures to a lightweight .NET architecture. Conducted daily sessions with ~10 business stakeholders to fully capture complex domain logic, resulting in significantly improved system stability, performance, and long-term maintainability.

Led the design and implementation of an end-to-end accounting system tailored for the insurance domain, handling domain-specific financial workflows from requirements gathering through delivery.
